

IEC Tariff and Solar Net-Metering Guide (Sample)

1. Standard Residential Tariff

Residential customers are billed under a tiered consumption structure. The first consumption tier is billed at the base rate, and consumption above the threshold is billed at the higher tier rate. Tier thresholds are published quarterly and are not fixed; agents should not quote a specific tier threshold from memory in any customer communication, since it changes by regulation.

2. Time-of-Use Plans

Time-of-use plans apply different rates depending on the hour of consumption, with lower rates typically offered during off-peak overnight hours. These plans benefit customers with predictable evening or overnight consumption, such as electric vehicle charging, and are usually unfavorable for customers whose consumption is concentrated in daytime peak hours.

3. Solar Net-Metering

Customers with a private solar installation are billed on a net basis: consumption is offset by generation exported to the grid within the same billing period. Net export that exceeds consumption in a given period is generally credited forward rather than paid out in cash, and the credit does not expire within the same annual cycle.

4. Smart Meter Upgrade Requests

Customers on legacy mechanical meters may request an upgrade to a smart meter. Upgrades are typically scheduled within a few weeks and require site access. Smart meters remove the need for periodic estimated reads, since consumption is reported automatically, which directly reduces billing disputes caused by estimate corrections.

5. Disconnection and Reconnection Policy

Disconnection for non-payment follows a mandatory written notice period before it can be carried out, and reconnection after payment is typically completed within one business day. Chat agents must never confirm or schedule a disconnection or reconnection directly; these actions require a human agent and are outside the scope of an automated assistant.
